Visual Analogue Scale (VAS)

Plusieurs auteurs depuis 1974

Instrument de mesure	Visual Analogue Scale
Abréviation	VAS
Auteur	Huskisson, E. C. (1974). Measurement of pain. *Lancet, 2,* 1127-1131.
Thème	Management des symptômes de la douleur
Objectif	Evaluer la douleur chez le patient
Population	Non spécifiée
Relevé	Dispensateur de soins
Nombre d'items	1 item
Présence du patient requise	Oui
Localisation de l'instrument de mesure	http://www.ndhcri.org/

Objectif

Contrôle de la douleur chez le patient à l'aide d'un autorapport sur une échelle à un item.

Groupe cible

Le groupe cible visé par la Visual Analogue Scale (VAS) est divers. La validité de l'instrument de mesure a déjà été étudiée chez des enfants/ adolescents (Stinson, Kavanagh, Yamada, Gill, & Stevens, 2006), chez des adultes (Bijur, Silver, & Gallagher, 2001; Carey, Turpin, Smith, Whatley, & Haddox, 1997), ainsi que chez des personnes âgées (Carey, Turpin, Smith, Whatley, & Haddox, 1997; Mawdsley, Moran, & Conniff, 2002; Pautex et al., 2006). Des études valident l'utilisation de la VAS pour diverses catégories de patients telles que les patients en service de chirurgie (Gagliese, Weizblit, Ellis,& Chan, 2005; Jensen, Chen, & Brugger; 2002), les déments (Pautex et al., 2005; Pautex et al., 2006), les patients souffrant de problèmes musculo-squelettiques (Mawdsley et al., 2002; Pomeroy et al., 2000; Tamiya et al., 2002; Triano, McGregor, Cramer, & Emde, 1993) et d'autres patients présentant des formes spécifiques de douleur (Crossley, Bennell, Cowan, & Green, 2004; Freeman, Smyth, Dallam, & Jackson, 2001; Gallagher, Bijur, Latimer, & Silver; 2002; Gagliese & Katz, 2003).

Par conséquent, l'utilisation de la VAS comme instrument de mesure pour le management de la douleur peut être généralisée pour une large population de patients.

Description

La VAS est une ligne de 100 mm dont les deux extrêmes sont limités par les termes « Aucune douleur » et « Pire douleur possible ». L'intention est que le patient indique sur la ligne l'intensité de la douleur qu'il ressent au moment du relevé. L'écart entre le point zéro (« Aucune douleur ») et le marquage du patient est ensuite mesuré en mm par le dispensateur de soins.

La version la plus connue de la VAS a une ligne d'orientation horizontale, bien qu'une orientation verticale soit aussi courante pour l'évaluation de la douleur du patient. Il existe de nombreuses variantes à la version originale de la VAS. Des différences se retrouvent notamment dans la terminologie que l'on utilise pour délimiter le point final (ex. douleur extrême, douleur la plus atroce, …), la présence de pointillés de séparation sur l'échelle et l'unité de longueur utilisée (cm ou mm).

Fiabilité

La VAS présente une haute fiabilité. Cela peut être amplement étayé à l'aide de résultats de différentes études qui ont déjà été réalisées.

De nombreuses études font état d'une *intra-rater reliability* de 0.90 et plus (Bijur et al., 2001; Mawdsley, 2002; Pautex et al. 2005; Pautex et al., 2006). Quelques études mentionnent même une valeur de 0.99 (Gallagher et al., 2002; McGrath et al., 1985 in Stinson et al., 2006). Le nombre d'études avec une faible *intra-rater reliability* (r < 0.75) est limité (Pomeroy et al., 2000; Tamiya et al., 2002). De plus, nous notons que les mesures répétées sont caractérisées, dans ces études, par de grands intervalles temporels (> 1 jour), ce qui explique peut-être la variabilité des scores de douleur à la suite de changements dans le vécu de la douleur.

Des résultats positifs sont également générés pour l'*interrater reliability*. Dans les études retrouvées, cette corrélation est toujours supérieure à 0.70 (Benaim et al, 2007; Herr, Spratt, Mobily, & Richardson, 2004; Pautex et al. 2005; Pautex et al., 2006).

Le coefficient *alpha de Cronbach* entre la VAS et d'autres échelles de mesure à un item a été vérifié dans l'étude de Herr et al. (2004) et dans l'étude de Carey et al. (1997). La corrélation atteignait respectivement α = 0.97 (VAS – Numeric Rating Scale – Verbal Descriptor Scale – Verbal Numeric Scale – Faces Pain Scale) et α = 0.88 (VAS – Faces Rating Scale – Numeric Rating Scale).

Validité

La VAS est un instrument de mesure valide pour l'appréciation de la douleur. Plusieurs études ont comparé des scores VAS de patients avec des scores sur d'autres échelles de douleur (Benaim et al, 2007; Freeman et al., 2001; Hicks, von Baeyer, Spafford, Korlaar, & Goodenough, 2001; Gagliese et al., 2005; Kim &

Buschmann, 2006; Mawdsley et al., 2002; Pautex et al. 2005; Pautex et al., 2006; Stinson et al., 2006; van Dijk, Koot, Saad, Tibboel, & Passchier, 2002). La corrélation plutôt importante entre la VAS et d'autres échelles de valeur valides confirme la *concurrent validity* de l'échelle.

Afin de vérifier la *construct validity* de la VAS, Gagliese et al. (2005) et Herr et al. (2004) ont effectué une *analyse des principaux composants.* Dans les deux études, 1 facteur a été abstrait au départ des scores de douleur sur les différents instruments de mesure à un item.

Des corrélations significatives ont également été rapportées entre des scores VAS et l'administration d'analgésiques (Abu-Saad & Holzemer in Stinson et al., 2006; Aradine et al. in Stinson et al., 2006; Gagliese & Katz, 2003; Tyler et al. in Stinson et al., 2006), le taux de protéine C réactive (Tamiya et al., 2002), l'intensité de la douleur causée (Herr et al., 2004), des observations comportementales chez des patients souffrant de douleurs (Koho, Aho, Watson, & Hurri, 2001), …

La *sensitivité* de la VAS est confirmée par des études avec un *repeated measures design* (Crossley et al., 2004; Jensen et al., 2002). Ces études ont corrélé les scores VAS de patients à des enregistrements de douleur entre les différentes mesures. Les évolutions de la douleur rapportées par les patients (« ma douleur a augmenté ou a diminué) étaient nettement rattachées aux scores VAS.

Utilisation de la VAS chez les enfants

La VAS a déjà été amplement étudiée chez les enfants et fait état d'une bonne validité pour la plupart des enfants à partir de l'âge de 8 ans (Champion et al. in Stinson et al., 2006). La VAS est toutefois moins indiquée pour les enfants de moins de 8. La fiabilité de l'instrument de mesure diminue dans cette catégorie d'âge (Beyer and Aradine in Stinson et al., 2006; Shields et al. in Stinson et al., 2006). La Faces Pain Scale peut représenter une possible alternative pour la population composée des enfants âgés de moins de 8 ans.

Utilisation de la VAS chez les personnes âgées

Une étude démontre que les personnes âgées peuvent éprouver des difficultés à compléter et à comprendre la VAS (Freeman et al., 2001; Herr, Mobily, Kohout & Wagenaar, 1998; Jensen & Karoly in Dworkin et al., 2005; Pautex et al., 2005; Pautex et al., 2006). C'est particulièrement le cas pour les personnes d'un âge avancé et les déments pour lesquels, par exemple, la Faces Pain Scale ou la Verbal Rating Scale sera plus indiquée.

Il est fait état de plus de problèmes avec l'utilisation de la VAS horizontale en comparaison avec la VAS verticale. La VAS verticale est recommandée, étant donné que cet instrument de mesure génèrerait moins de relevés erronés et serait plus facilement compréhensible pour les personnes âgées (Gagliese et al., 2005).

Convivialité

La convivialité de la VAS a été évaluée par 33 dispensateurs de soins travaillant dans les services d'oncologie médicale/radiothérapie et d'oncologie pédiatrique de l'hôpital universitaire de Gand.

94% des personnes interrogées constatent que la VAS peut être relevée en moins de 3 minutes. De plus, la plupart des dispensateurs de soins sont d'avis que la VAS est simple à compléter (85%) et est claire et univoque (91%). Le mode d'emploi est également précis pour 94% des dispensateurs de soins. L'évaluation de la convivialité de la VAS est donc extrêmement positive. Notons toutefois que 1 dispensateur de soins sur 2 est d'avis qu'une formation complémentaire est requise pour l'utilisation de l'instrument de mesure.

Remarques

Plusieurs études font état de difficultés chez des patients pour compléter la VAS (Gagliese et al., 2005; Herr et al., 2004; Paice & Cohen 1997; Pautex et al., 2006). Des comparaisons entre la VAS et la Numeric Rating Scale (NRS) montrent que l'utilisation de cette dernière échelle pose moins de problèmes. De plus, la NRS bénéficie aussi d'une fiabilité/validité élevée et comparable. En outre, les patients indiquent eux-mêmes qu'ils préfèrent la NRS et d'autres échelles de douleur à la VAS (Carey et al., 1997; Dworkin et al., 2005; Gagliese et al., 2005; Herr et al., 2004; Paice & Cohen 1997). Cela peut indiquer que la NRS est plus indiquée que la VAS pour l'évaluation de la douleur. Plusieurs études de validation recommandent donc la NRS comme étant l'instrument le plus adéquat pour l'évaluation de la douleur (Downie et al., 1978; Dworkin et al., 2005; Jensen et al., 2003). Cela doit être quelque peu nuancé, étant donné qu'aucune échelle de douleur ne peut être utilisée pour toutes les formes de douleur ou pour toutes les catégories d'âge.

VISUAL ANALOGUE SCALE (VAS)

VERSCHEIDENE AUTEURS SINDS1974

Author (year)	Setting	Sample (n)	Design	Reliability	Validity
Pautex, S., Michon, A., Guedira, M., Emond, H., Le Lous, P., Samaras, D. et al. (2006)	Geriatrics hospital and a geriatric psychiatry service.	129 patients aged 65 and older hospitalized during a 15 month-period who met DSM criteria for dementia, with a Mini-Mental State Examination score less than 11 and a Clinical Dementia Rating of 3 or greater. (n = 129)	Repeated measures design: Patients were asked to indicate their current level of pain on different scales (VAS, Faces Pain Scale and Verbal Rating Scale). This was repeated 30 minutes later either by the same investigator (50% of the cases) or by a different examiner who was blinded to the first assessment.	S E	CrV
Gagliese, L., Weizblit, N., Ellis, W., & Chan, V. W. (2005)	Toronto General Hospital, University Health Network and Mount Sinai Hospital, Toronto, Ontario.	Patients scheduled to receive patient-controlled analgesia following general surgery. (n = 504)	Comparative study: the VAS was compared with the Numeric Rating Scale (NRS), the Verbal Descriptor Scale (VDS) and the pain intensity measures of the McGill Pain Questionnaire (MPQ).		FV CrV CsV

Reliability: Stability (S), Internal consistency (IC), Equivalence (E)
Validity: Face validity (FV), Content validity (CtV), Criterion validity (CrV), Construct validity (CsV)
Sensitivity (Sen), Specificity (Sp), Positive Predictive Value (PPV), Negative Predictive Value (NPV), Receiver Operating Curve (ROC), Likelihood Ratio (LR), Odds Ratio (OR)

Results reliability	Results validity	Commentary

(S) *Intra-rater reliability:*
R = 0.98 (p < 0.001)
 	
(E) *Interrater reliability:*
R = 0.88 (p < 0.001)
	(CrV) *Concurrent validity:*
	- Correlation between VAS and different scales at first assessment:
	  13. Correlation VAS – Verbal Rating Scale: r = 0.67 (p<0.001)
	  14. Correlation VAS – Faces Pain Scale: r = 0.45 (p<0.001)
	  15. Correlation VAS – Doloplus 2 (observational pain scale): r = 0.25
	    (p<0.001)
	- Correlation between VAS and different scales at second assessment:
	  16. Correlation VAS – Verbal Rating Scale: r = 0.73 (p<0.001)
	  17. Correlation VAS – Faces Pain Scale: r = 0.66 (p<0.001)
	  18. Correlation VAS – Doloplus 2 (observational pain scale): r = 0.24
	    (p<0.001)
		Weak correlations between VAS and Doloplus 2.
		
		A significant better comprehension of the Verbal Rating Scale (VRS) and the Faces Pain Scale (FPS) scale was found. This might suggest that the VAS is not the most appropriate pain assessment scale for patients with severe dementia.

	(FV) *Face validity;*
	Patients rated the VAS as the least accurate and least preferred instrument for future assessments.The VAS had the highest proportion of patients making errors (p ≤ 0.005).
	
	(CrV) *Concurrent validity:*
	- Correlation between VAS and VDS and NRS:
	  5. Patients aged > 60 years: r = 0.60-0.93 (p<0.001)
	  6. Patients aged ≤ 60 years: r = 0.72-0.91 (p<0.001)
	- Correlation between VAS and MPQ was lower.
	
	(CsV) *Principal components analysis:*
	A one-factor model was extracted from the different measurement scales and accounted for 82% of the total variance in the young group and 85% of the variance in the older group. Factor loadings were 0.95 for horizontal VAS and 0.91 for vertical VAS.
		The vertical VAS was associated with lower error rates and greater face validity than the horizontal VAS.

Reliability: Stability (S), Internal consistency (IC), Equivalence (E)
Validity: Face validity (FV), Content validity (CtV), Criterion validity (CrV), Construct validity (CsV)
Sensitivity (Sen), Specificity (Sp), Positive Predictive Value (PPV), Negative Predictive Value (NPV), Receiver Operating Curve (ROC), Likelihood
Ratio (LR), Odds Ratio (OR)

Author (year)	Setting	Sample (n)	Design	Reliability	Validity
Freeman, K., Smyth, C., Dallam, L., & Jackson, B. (2001)	Hospital.	Adults who had one or more stage 1 to 4 pressure ulcer, and had some ability to explain their pain experience. (n = 44)	Comparative study: the VAS was compared with the Faces Rating Scale (FRS).		CrV
Gallagher, E. J., Bijur, P. E., Latimer, C., & Silver, W. (2002)	2 urban emergency departments.	Convenience sample of patients with the chief complaint of acute abdominal pain. (n = 101)	Repeated measures design: VAS measurements 1 minute apart every 30 minutes over two hours.	S	Sen
Jensen, M. P., Chen, C., & Brugger, A. M. (2002)	Not specified.	123 patients who had undergone knee surgery and 124 women who had undergone a laparatomy . (n = 227)	Repeated measures design. Baseline measurement with 16 additional measures up to 24h following surgery.		Sen

Reliability: Stability (S), Internal consistency (IC), Equivalence (E)
Validity: Face validity (FV), Content validity (CtV), Criterion validity (CrV), Construct validity (CsV) Sensitivity (Sen), Specificity (Sp), Positive Predictive Value (PPV), Negative Predictive Value (NPV), Receiver Operating Curve (ROC), Likelihood Ratio (LR), Odds Ratio (OR)

Results reliability	Results validity	Commentary
	(CrV) *Concurrent validity:* A mathematical transformation of the FRS in a numeric value was highly correlated with the VAS ($r = 0.92$). There was a significant increase in variability in VAS with increasing values of the FRS ($p < 0.05$).	
(S) *Intrarater reliability:* $r = 0.99$ (95% CI 0.989 to 0.992). *Bland-Altman analyses:* 50 percent of the differences between the repeated VAS scores (time 0 and 1 minute later) were between -3mm and +2mm, 90 % were between -8mm and + 9mm, and 95% of the scores were within ±11mm of the 100 mm VAS.	**(Sen)** After completing the VAS at the end of each 30 minute interval, patients were also asked to contrast current pain with their pain at the previous using one of 5 categorical descriptors: 'much less pain', 'a little less pain', 'about the same pain', 'a little more pain', or 'much more pain'. Differences in VAS scores increased linearly as pain descriptors escalated from 'much less' to 'much more pain' ($F = 79.4$, $p < 0.001$).	
	(Sen) *Repeated measures ANOVA:* Dependent variables: VAS and VRS pre- to post treatment difference scores Independent variables: time and analgeticum treatment - VAS tended to be more sensitive than VRS showing the smallest F values ($p < 0.001$). - A composite measure made up of a standardized average of three measures of outcome (VAS difference score, VRS difference score and a pain relief rating was not more sensitive to treatment effects (analgetica) than any one measure.	

Reliability: Stability (S), Internal consistency (IC), Equivalence (E)

Results reliability	Results validity	Commentary
(IC) *Internal consistency:* Intercorrelations between the scales were all statistically significant at every temperature (p < 0.001). *Cronbach's alpha within each scale across the 7 temperature values:* VAS: 0.88 NRS: 0.88 VDS: 0.86 VNS: 0.88 FPS: 0.88 *Cronbach's alpha within temperature across the 5 scales:* 43°C: 0.96 45°C: 0.96 46°C 0.96 47°C: 0.97 48°C: 0.97 49°C: 0.97 51°C: 0.97 **(E)** *Interrater reliability:* VAS: 93.5% agreement NRS: 100% agreement VDS: 100% agreement VNS: 100% agreement FPS: 100% agreement	**(CsV)** *Principal components analysis:* A one-factor model was extracted from the different measurement scales. The correlation of each scale to the isolated factor was as follows: VAS: 0.94 NRS: 0.96 VDS: 0.95 VNS: 0.95 FPS: 0.86 **(Sen)** Each tool demonstrated significant increases in score associated with increase in temperature (p < 0.001).	The VAS had a significant higher failure rate (6.7%) in comparison with the NRS, VDS, VNS, and FPS. The VNS demonstrated significantly higher levels of pain report than the other 4 scales. The psychometric scale evaluation was conducted using an experimental pain stimulus instead of using clinical pain stimili. The scales most preferred in order by the total sample: NRS (35.3%); VDS (25.3%); VNS (15.9%); FPS (12.9%); VAS (10.6%).

Results reliability	Results validity	Commentary
	(CrV) *Concurrent validity:* There were significant moderate interscale correlations in both age groups. In the older group, on POD 1, the correlations between MPQ and both VAS ratings, and between PPI and VAS-M, failed to reach significance. The remaining correlations were significant. On POD 2, the only nonsignificant correlation was between VAS-M and MPQ. The magnitude of the correlations did not differ between the groups except for VAS-R and MPQ. On both POD 1 ($p \leq 0.05$) and POD 2 ($p \leq 0.004$), this correlation was lower in older than younger patients. **(CsV)** *Convergent validity:* On all scales, there was a significant decrease in scores with time. The amount of morphine self-administered also decreased over time in both groups but the decrease (POD 1 minus POD 2) was greater in the younger (27.68 ± 22.93 mg) than the older (20.51 ± 19.58 mg) patients ($p \leq 0.02$).	
(S) *Intra-rater reliability VAS Pain at the same day of administration (n = 47):* r = 0.84 (95% CI = 0.78–0.88) *Intra-rater reliability VAS Pain measured 7 days after the initial measurement (n = 47):* r = 0.64 (95% CI = 0.43–0.78)	**(CsV)** *Convergent validity:* - VAS Pain was moderately positively correlated with VAS Anxiety (0.49, $p < 0.001$) and VAS Depression (0.36, $p < 0.001$) and moderately negatively correlated with VAS Life satisfaction (-0.23, $p < 0.05$). - VAS Anxiety explained 30% of the variance in pain (F = 21.1; d.f. = 1, 49; $p < 0.001$). - VAS Depression explained 17% of the variance in VAS Pain (F = 9.8; d.f. = 1, 49; $p = 0.003$). - Higher CRP levels were associated with greater pain (F = 6.09; d.f. = 4, 95; $p = 0.015$).	Day-to-day variation could account for some of the lack of intra-rater agreement 7 days after the initial measurement.

Results reliability	Results validity	Commentary
	(CrV) *Concurrent validity:* Results indicate that pain intensities by the FPS, the NRS and the VAS were not significantly different (F(1.00, 68.00) = 2.93, p = 0.09); likewise the tools were not different in reporting the intensity of patient's pain. The VAS had moderately strong correlation with the FPS (r = 0.73, p < 0.001) and the NRS (r = 0.91, p < 0.001). Correlation between the VAS and the NRS of the cognitively impaired group (r = 0.88, p < 0.001) was weaker than the correlation of the cognitively intact group (r = 0.92, p < 0.001), correlation between the FPS and the NRS of the cognitively impaired group (r = 0.75, p< 0.001) was slightly stronger than correlation of the cognitively intact group (r = 0.70, p< 0.001).

Qu'est-ce que BEST ?
BEST pour Belgian Screening Tools est le nom d'une étude réalisée par l'Université de Gand, service des Sciences Infirmières, à la demande du Service Public Fédéral de la Santé Publique, Sécurité Alimentaire et Environnement.

Objectif de BEST ?
Le but de ce projet est de construire une base de données contenant des instruments de mesures validés scientifiquement. Dans le but d'objectiver les diagnostics et résultats des interventions infirmières, des instruments de mesures fiables et valides doivent être disponibles pour démontrer l'efficience des soins infirmiers.
Notre attention se porte sur les instruments de mesure utilisables pour scorer les interventions infirmières du nouveau Résumé Infirmier Minimum ou DI-RHM.

Que pouvez-vous trouver dans ce rapport ?
Le rapport décrit les différents instruments de mesure. En plus, si nous en avons reçu l'autorisation des auteurs, l'instrument est mis à votre disposition. Les instruments de mesure présentant une fiabilité et une validité élevées ont également fait l'objet d'une traduction vers le néerlandais et le français.
